

# Expected Norms of Zero-One Polynomials

Peter Borwein, Kwok-Kwong Stephen Choi, and Idris Mercer

*Abstract.* Let  $\mathcal{A}_n = \{a_0 + a_1z + \dots + a_{n-1}z^{n-1} : a_j \in \{0, 1\}\}$ , whose elements are called *zero-one polynomials* and correspond naturally to the  $2^n$  subsets of  $[n] := \{0, 1, \dots, n-1\}$ . We also let  $\mathcal{A}_{n,m} = \{\alpha(z) \in \mathcal{A}_n : \alpha(1) = m\}$ , whose elements correspond to the  $\binom{n}{m}$  subsets of  $[n]$  of size  $m$ , and let  $\mathcal{B}_n = \mathcal{A}_{n+1} \setminus \mathcal{A}_n$ , whose elements are the zero-one polynomials of degree exactly  $n$ .

Many researchers have studied norms of polynomials with restricted coefficients. Using  $\|\alpha\|_p$  to denote the usual  $L_p$  norm of  $\alpha$  on the unit circle, one easily sees that  $\alpha(z) = a_0 + a_1z + \dots + a_Nz^N \in \mathbb{R}[z]$  satisfies  $\|\alpha\|_2^2 = c_0$  and  $\|\alpha\|_4^4 = c_0^2 + 2(c_1^2 + \dots + c_N^2)$ , where  $c_k := \sum_{j=0}^{N-k} a_j a_{j+k}$  for  $0 \leq k \leq N$ .

If  $\alpha(z) \in \mathcal{A}_{n,m}$ , say  $\alpha(z) = z^{\beta_1} + \dots + z^{\beta_m}$  where  $\beta_1 < \dots < \beta_m$ , then  $c_k$  is the number of times  $k$  appears as a difference  $\beta_i - \beta_j$ . The condition that  $\alpha \in \mathcal{A}_{n,m}$  satisfies  $c_k \in \{0, 1\}$  for  $1 \leq k \leq n-1$  is thus equivalent to the condition that  $\{\beta_1, \dots, \beta_m\}$  is a *Sidon set* (meaning all differences of pairs of elements are distinct).

In this paper, we find the average of  $\|\alpha\|_4^4$  over  $\alpha \in \mathcal{A}_n$ ,  $\alpha \in \mathcal{B}_n$ , and  $\alpha \in \mathcal{A}_{n,m}$ . We further show that our expression for the average of  $\|\alpha\|_4^4$  over  $\mathcal{A}_{n,m}$  yields a new proof of the known result: if  $m = o(n^{1/4})$  and  $B(n, m)$  denotes the number of Sidon sets of size  $m$  in  $[n]$ , then almost all subsets of  $[n]$  of size  $m$  are Sidon, in the sense that  $\lim_{n \rightarrow \infty} B(n, m) / \binom{n}{m} = 1$ .

## 1 Introduction and Statement of Main Result

We let  $\mathcal{A}_n$  denote the set  $\{a_0 + a_1z + \dots + a_{n-1}z^{n-1} : a_j \in \{0, 1\} \text{ for all } j\}$ , and we call the elements of  $\mathcal{A}_n$  *zero-one polynomials*. There is a natural bijection between the  $2^n$  polynomials in  $\mathcal{A}_n$  and the  $2^n$  subsets of  $[n] := \{0, 1, \dots, n-1\}$ . Generally, if  $\alpha(z) \in \mathcal{A}_n$ , we define

$$m := \alpha(1) = \text{the number of coefficients of } \alpha(z) \text{ that are } 1,$$

and we write  $\alpha(z) = z^{\beta_1} + z^{\beta_2} + \dots + z^{\beta_m}$  where  $\beta_1 < \beta_2 < \dots < \beta_m$ , so  $\{\beta_1, \beta_2, \dots, \beta_m\}$  is the subset of  $[n]$  that corresponds to  $\alpha(z)$ . We let  $\mathcal{A}_{n,m}$  denote the set  $\{\alpha(z) \in \mathcal{A}_n : \alpha(1) = m\}$ , so  $|\mathcal{A}_{n,m}| = \binom{n}{m}$  and  $\mathcal{A}_n = \mathcal{A}_{n,0} \cup \mathcal{A}_{n,1} \cup \dots \cup \mathcal{A}_{n,n}$ . We also define  $\mathcal{B}_n := \mathcal{A}_{n+1} \setminus \mathcal{A}_n$ , so  $\mathcal{B}_n$  consists of the  $2^n$  zero-one polynomials of degree exactly  $n$ .

A recurring theme in the literature is the problem of finding a polynomial with “small” norm subject to some restriction on its coefficients. (See [3, Problem 26], [5, Problem 19], or [1, Ch. 4, 15].) In general, for

$$(1.1) \quad \alpha(z) = a_0 + a_1z + \dots + a_Nz^N \in \mathbb{R}[z],$$

we define the usual  $L_p$  norms of  $\alpha(z)$  on the unit circle:

$$\|\alpha\|_p := \left( \frac{1}{2\pi} \int_0^{2\pi} |\alpha(e^{i\theta})|^p d\theta \right)^{1/p},$$

where  $p \geq 1$  is real. The main result of this paper, which appears as Theorem 4.1 in Section 4, is that if  $n \geq 4$  and  $m \leq n$ , we have

$$\begin{aligned} \mathbf{E}_{\mathcal{A}_n}(\|\alpha\|_4^4) &= \frac{4n^3 + 42n^2 - 4n + 3 - 3(-1)^n}{96}, \\ \mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4) &= 2m^2 - m + \frac{2m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(2n^2 - 4n + 1 - (-1)^n)}{2n^{[4]}}, \\ \mathbf{E}_{\mathcal{B}_n}(\|\alpha\|_4^4) &= \frac{4n^3 + 66n^2 + 188n + 87 + 9(-1)^n}{96}, \end{aligned}$$

where  $\mathbf{E}_\Omega(\|\alpha\|_4^4)$  denotes the average of  $\|\alpha\|_4^4$  over the polynomials in  $\Omega$ , and the notation  $x^{[k]}$  is shorthand for  $x(x-1)\cdots(x-k+1)$ . This complements results of Newman and Byrnes [7], who found the average of  $\|\alpha\|_4^4$  over the  $2^n$  polynomials of the form

$$(1.2) \quad a_0 + a_1z + \cdots + a_{n-1}z^{n-1}, \quad a_j \in \{+1, -1\} \text{ for all } j,$$

and Borwein and Choi [2], who found (among other things) the average of  $\|\alpha\|_6^6$  and  $\|\alpha\|_8^8$  over the  $2^n$  polynomials of the form (1.2), and the average of  $\|\alpha\|_2^2$ ,  $\|\alpha\|_4^4$ , and  $\|\alpha\|_6^6$  over the  $3^n$  polynomials of the form

$$a_0 + a_1z + \cdots + a_{n-1}z^{n-1}, \quad a_j \in \{+1, 0, -1\} \text{ for all } j.$$

## 2 Autocorrelation

Notice that if  $\alpha$  is of the form (1.1) and  $|z| = 1$ , we have

$$\begin{aligned} |\alpha(z)|^2 &= \alpha(z)\overline{\alpha(z)} = (a_0 + a_1z + \cdots + a_Nz^N) \left( a_0 + a_1\frac{1}{z} + \cdots + a_N\frac{1}{z^N} \right) \\ &= c_N\frac{1}{z^N} + \cdots + c_1\frac{1}{z} + c_0 + c_1z + \cdots + c_Nz^N, \end{aligned}$$

where the  $c_k$  are the so-called (*aperiodic*) autocorrelations of  $\alpha$ , defined for  $0 \leq k \leq N$  by  $c_k := \sum_{j=0}^{N-k} a_j a_{j+k}$ . Using the general fact that

$$\frac{1}{2\pi} \int_0^{2\pi} \left( b_{-M}\frac{1}{z^M} + \cdots + b_{-1}\frac{1}{z} + b_0 + b_1z + \cdots + b_Mz^M \right) d\theta = b_0, \quad (z = e^{i\theta}),$$

we see that for  $\alpha$  of the form (1.1), we have

$$\|\alpha\|_2^2 = \frac{1}{2\pi} \int_0^{2\pi} \left( c_N\frac{1}{z^N} + \cdots + c_1\frac{1}{z} + c_0 + c_1z + \cdots + c_Nz^N \right) d\theta = c_0, \quad (z = e^{i\theta}),$$

and

$$(2.1) \quad \begin{aligned} \|\alpha\|_4^4 &= \frac{1}{2\pi} \int_0^{2\pi} \left( c_N \frac{1}{z^N} + \cdots + c_1 \frac{1}{z} + c_0 + c_1 z + \cdots + c_N z^N \right)^2 d\theta \\ &= c_N^2 + \cdots + c_1^2 + c_0^2 + c_1^2 + \cdots + c_N^2 = c_0^2 + 2(c_1^2 + \cdots + c_N^2), \quad (z = e^{i\theta}). \end{aligned}$$

We further observe that

$$\begin{aligned} c_k^2 &= \left( \sum_{j=0}^{N-k} a_j a_{j+k} \right)^2 = \sum_{i=0}^{N-k} a_i a_{i+k} \cdot \sum_{j=0}^{N-k} a_j a_{j+k} = \sum_{i=0}^{N-k} \sum_{j=0}^{N-k} a_i a_j a_{i+k} a_{j+k} \\ &= \sum_{i=0}^{N-k} \sum_{j=0}^{N-k} f(i, j). \end{aligned}$$

Noting that  $f(i, j) := a_i a_j a_{i+k} a_{j+k}$  satisfies  $f(i, j) = f(j, i)$ , we have

$$(2.2) \quad \begin{aligned} c_k^2 &= \sum_{i=0}^{N-k} \sum_{j=0}^{N-k} f(i, j) = \sum_{i=0}^{N-k} f(i, i) + 2 \sum_{0 \leq i < j \leq N-k} f(i, j) \\ &= \sum_{i=0}^{N-k} a_i^2 a_{i+k}^2 + 2 \sum_{0 \leq i < j \leq N-k} a_i a_j a_{i+k} a_{j+k}. \end{aligned}$$

If  $\alpha(z) = a_0 + \cdots + a_{n-1} z^{n-1} = z^{\beta_1} + \cdots + z^{\beta_m} \in \mathcal{A}_{n,m}$ , then we have  $c_0 = m$  and  $c_k$  is the number of  $j$  such that  $a_j$  and  $a_{j+k}$  are both 1 and is equal to the number of times  $k$  appears as a difference  $\beta_i - \beta_j$ . Thus  $c_1 + \cdots + c_{n-1} = m(m-1)/2$ , and since the  $c_k$  are nonnegative integers, we have

$$(2.3) \quad c_1^2 + \cdots + c_{n-1}^2 \geq c_1 + \cdots + c_{n-1} = m(m-1)/2$$

with equality if and only if  $c_k \in \{0, 1\}$  for  $1 \leq k \leq n-1$ , or in other words, if and only if all differences of pairs of elements of  $\{\beta_1, \dots, \beta_m\}$  are distinct. If all differences of pairs of elements of  $\{\beta_1, \dots, \beta_m\}$  are distinct, we call  $\{\beta_1, \dots, \beta_m\}$  a *Sidon set*.

Using (2.1), we see that (2.3) and  $c_0 = m$  prove the following.

**Proposition 2.1** *For any  $\alpha(z) = z^{\beta_1} + \cdots + z^{\beta_m} \in \mathcal{A}_{n,m}$ , we have  $\|\alpha\|_4^4 \geq 2m^2 - m$ , with equality if and only if  $\{\beta_1, \dots, \beta_m\}$  is a Sidon set.*

We observe also that (2.3) implies that  $c_1^2 + \cdots + c_{n-1}^2 - m(m-1)/2$  is a nonnegative integer, and is zero if and only if  $\{\beta_1, \dots, \beta_m\}$  is Sidon.

### 3 Some Facts and Notation

If  $\Omega$  denotes  $\mathcal{A}_n, \mathcal{B}_n$ , or  $\mathcal{A}_{n,m}$ , then we turn  $\Omega$  into a probability space by giving each polynomial  $\alpha \in \Omega$  equal weight  $p(\alpha)$ .

Generally, we will denote a typical element of  $\mathcal{A}_n$  or  $\mathcal{A}_{n,m}$  by

$$\alpha(z) = a_0 + a_1z + \cdots + a_{n-1}z^{n-1},$$

and denote a typical element of  $\mathcal{B}_n$  by  $\alpha(z) = a_0 + a_1z + \cdots + a_{n-1}z^{n-1} + z^n$ . As in Section 1, if  $\alpha \in \mathcal{A}_{n,m}$ , we also write

$$\alpha(z) = z^{\beta_1} + z^{\beta_2} + \cdots + z^{\beta_m}$$

where  $\beta_1 < \beta_2 < \cdots < \beta_m$ .

If  $\Omega$  is one of the three spaces  $\mathcal{A}_n$ ,  $\mathcal{B}_n$ , or  $\mathcal{A}_{n,m}$  and  $X$  is a random variable on  $\Omega$ , we of course have  $\mathbf{E}_\Omega(X) = \sum_{\alpha \in \Omega} X(\alpha)p(\alpha)$ , and we will sometimes omit the subscript  $\Omega$  if it is clear from the context what probability space we are considering.

Two facts we will use that are each immediate from first principles are *Markov's inequality*,  $\Pr[X \geq a] \leq \mathbf{E}(X)/a$ , where  $X$  is a nonnegative real random variable, and *linearity of expectation*,  $\mathbf{E}(X_1 + \cdots + X_k) = \mathbf{E}(X_1) + \cdots + \mathbf{E}(X_k)$ , which holds regardless of dependence or independence of the  $X_i$ .

#### 4 Calculation of $\mathbf{E}(\|\alpha\|_4^4)$

Let  $j_1, j_2, j_3, j_4$  denote distinct integers. We begin this section by finding some averages of products of  $a_{j_i}$  that we will need later. First, suppose our probability space  $\Omega$  is  $\mathcal{A}_n$ . We then have

$$(4.1) \quad \mathbf{E}(a_{j_1}a_{j_2}) = \frac{1}{2^n}(\text{number of } \alpha \in \mathcal{A}_n \text{ such that } a_{j_1} = a_{j_2} = 1) = \frac{2^{n-2}}{2^n} = \frac{1}{4},$$

and by similar reasoning, we have

$$(4.2) \quad \mathbf{E}(a_{j_1}a_{j_2}a_{j_3}) = 1/8, \quad \mathbf{E}(a_{j_1}a_{j_2}a_{j_3}a_{j_4}) = 1/16.$$

Now suppose our probability space  $\Omega$  is  $\mathcal{A}_{n,m}$ . We then have

$$(4.3) \quad \begin{aligned} \mathbf{E}(a_{j_1}a_{j_2}) &= \frac{1}{\binom{n}{m}}(\text{number of } \alpha \in \mathcal{A}_{n,m} \text{ such that } a_{j_1} = a_{j_2} = 1) \\ &= \frac{\binom{n-2}{m-2}}{\binom{n}{m}} = \frac{m(m-1)}{n(n-1)} = \frac{m^{[2]}}{n^{[2]}}, \end{aligned}$$

and by similar reasoning, we have

$$(4.4) \quad \mathbf{E}(a_{j_1}a_{j_2}a_{j_3}) = m^{[3]}/n^{[3]}, \quad \mathbf{E}(a_{j_1}a_{j_2}a_{j_3}a_{j_4}) = m^{[4]}/n^{[4]}.$$

We note that we need  $n \geq 4$  in order for all expressions in (4.3) and (4.4) to be defined. For  $\Omega = \mathcal{A}_{n,m}$ , the case  $n \leq 3$  will be treated separately.

Now if  $\Omega$  is either of the probability spaces  $\mathcal{A}_n$  or  $\mathcal{A}_{n,m}$ , then equation (2.2) gives

$$(4.5) \quad c_k^2 = \sum_{i=0}^{n-k-1} a_i a_{i+k} + 2 \sum_{0 \leq i < j \leq n-k-1} a_i a_{i+k} a_j a_{j+k}.$$

We define  $\lambda := n - k$  and also define

$$(4.6) \quad S := \sum_{i=0}^{\lambda-1} a_i a_{i+k},$$

$$(4.7) \quad T := \sum_{0 \leq i < j \leq \lambda-1} a_i a_j a_{i+k} a_{j+k},$$

which of course implies  $c_k^2 = S + 2T$ . If  $k = 0$ , then  $c_k^2 = m^2$ . So if  $\Omega = \mathcal{A}_{n,m}$ , we have simply  $\mathbf{E}(c_0^2) = m^2$ , whereas if  $\Omega = \mathcal{A}_n$ , we have

$$(4.8) \quad \mathbf{E}(c_0^2) = \sum_{m=0}^n \frac{\binom{n}{m}}{2^n} m^2.$$

It is an exercise to see that the right side of (4.8) evaluates to  $(n^2 + n)/4$ . Alternatively, we may observe that  $c_0$  has a binomial distribution with parameters  $n$  and  $1/2$ , which implies

$$(4.9) \quad \mathbf{E}(c_0^2) = \mathbf{Var}(c_0) + \mathbf{E}(c_0)^2 = n \cdot \frac{1}{2} \cdot \frac{1}{2} + \left(n \cdot \frac{1}{2}\right)^2 = \frac{n^2 + n}{4}.$$

Having found  $\mathbf{E}(c_0^2)$  for  $\Omega = \mathcal{A}_{n,m}$  and for  $\Omega = \mathcal{A}_n$ , we now shift our attention to  $\mathbf{E}(c_k^2)$  for  $k \neq 0$ .

Assume  $k \neq 0$ , and observe that (4.5), (4.6), and (4.7) (and linearity of expectation) give us

$$(4.10) \quad \mathbf{E}(c_k^2) = \mathbf{E}(S) + 2\mathbf{E}(T) = \sum_{i=0}^{\lambda-1} \mathbf{E}(a_i a_{i+k}) + 2 \sum_{0 \leq i < j \leq \lambda-1} \mathbf{E}(a_i a_j a_{i+k} a_{j+k}).$$

Since  $k \neq 0$ , each of the  $\lambda$  terms in the sum  $\mathbf{E}(S)$  is of the form  $\mathbf{E}(a_{j_1} a_{j_2})$  where  $j_1 \neq j_2$ . We thus have

$$(4.11) \quad \mathbf{E}(S) = \begin{cases} \lambda/4 & \text{if } \Omega = \mathcal{A}_n, \\ \lambda m^{[2]}/n^{[2]} & \text{if } \Omega = \mathcal{A}_{n,m}, \end{cases}$$

by (4.1) and (4.2). As for the  $\binom{\lambda}{2}$  terms in the sum  $\mathbf{E}(T)$ , each term is of the form  $\mathbf{E}(a_i a_j a_{i+k} a_{j+k})$ . Since  $k \neq 0$  and  $i < j$ , the four subscripts  $i, j, i+k, j+k$  constitute either three distinct integers (if  $j = i+k$ ) or four distinct integers (if  $j \neq i+k$ ). If  $\{i, j, i+k, j+k\}$  consists of three distinct integers  $j_1, j_2, j_3$  where  $j_3$  is the one that is

“repeated”, then, since  $a_j \in \{0, 1\}$  for all  $j$ , we have  $\mathbf{E}(a_i a_j a_{i+k} a_{j+k}) = \mathbf{E}(a_{j_1} a_{j_2} a_{j_3}^2) = \mathbf{E}(a_{j_1} a_{j_2} a_{j_3})$ , whereas, of course, if  $\{i, j, i+k, j+k\}$  consists of four distinct integers, then  $\mathbf{E}(a_i a_j a_{i+k} a_{j+k})$  is of the form  $\mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4})$ . Therefore, we now ask the question: For which of the  $\binom{\lambda}{2}$  terms in the sum  $\mathbf{E}(T)$  does the set  $\{i, j, i+k, j+k\}$  consist of only three distinct integers?

For some  $i \in \{0, 1, \dots, \lambda-1\}$ , there is exactly one  $j$  satisfying both  $i < j \leq \lambda-1$  and  $j = i+k$ , and for other values of  $i$ , there is no such  $j$ . We will say that  $i$  is of “type I” if the former criterion holds, and is of “type II” if the latter criterion holds. An integer  $i$  is of type I if and only if  $i+k < \lambda$ , or equivalently,  $i < \lambda-k = n-2k$ . If  $n-2k \leq 0$  (i.e., if  $k \geq \lceil n/2 \rceil$ ), then  $i < n-2k$  never happens, i.e., no  $i$  is of type I and so all of the  $\binom{\lambda}{2}$  terms in the sum  $\mathbf{E}(T)$  are of the form  $\mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4})$ . On the other hand, if  $n-2k > 0$  (i.e., if  $k < \lceil n/2 \rceil$ ), then  $i < n-2k = \lambda-k$  sometimes happens; namely, it happens if and only if  $i$  is one of the  $\lambda-k$  integers  $0, 1, \dots, \lambda-k-1$ . In that case, each of those  $\lambda-k$  values of  $i$  is of type I, which implies that precisely  $\lambda-k$  of the  $\binom{\lambda}{2}$  terms in the sum  $\mathbf{E}(T)$  are of the form  $\mathbf{E}(a_{j_1} a_{j_2} a_{j_3})$  and the remaining terms are of the form  $\mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4})$ .

This implies that we have

$$\mathbf{E}(T) = \begin{cases} \binom{\lambda}{2} \mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4}) & \text{if } k \geq \lceil n/2 \rceil, \\ \binom{\lambda}{2} \mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4}) \\ \quad + (\lambda-k) [\mathbf{E}(a_{j_1} a_{j_2} a_{j_3}) - \mathbf{E}(a_{j_1} a_{j_2} a_{j_3} a_{j_4})] & \text{if } k < \lceil n/2 \rceil. \end{cases}$$

Thus, if  $\Omega = \mathcal{A}_n$ , then

$$\mathbf{E}(T) = \begin{cases} \binom{\lambda}{2}/16 & \text{if } k \geq \lceil n/2 \rceil, \\ \binom{\lambda}{2}/16 + (\lambda-k)/16 & \text{if } k < \lceil n/2 \rceil, \end{cases}$$

and hence by (4.10) and (4.11),

$$\mathbf{E}(c_k^2) = \begin{cases} \lambda/4 + \lambda(\lambda-1)/16 & \text{if } k \geq \lceil n/2 \rceil, \\ \lambda/4 + \lambda(\lambda-1)/16 + 2(\lambda-k)/16 & \text{if } k < \lceil n/2 \rceil. \end{cases}$$

On the other hand, if  $\Omega = \mathcal{A}_{n,m}$ , then

$$\mathbf{E}(T) = \begin{cases} \binom{\lambda}{2} m^{[4]}/n^{[4]} & \text{if } k \geq \lceil n/2 \rceil, \\ \binom{\lambda}{2} m^{[4]}/n^{[4]} + (\lambda-k) [m^{[3]}/n^{[3]} - m^{[4]}/n^{[4]}] & \text{if } k < \lceil n/2 \rceil, \end{cases}$$

and hence

$$\mathbf{E}(c_k^2) = \begin{cases} \lambda \frac{m^{[2]}}{n^{[2]}} + \lambda(\lambda-1) \frac{m^{[4]}}{n^{[4]}} & \text{if } k \geq \lceil n/2 \rceil, \\ \lambda \frac{m^{[2]}}{n^{[2]}} + \lambda(\lambda-1) \frac{m^{[4]}}{n^{[4]}} + 2(\lambda-k) \left[ \frac{m^{[3]}}{n^{[3]}} - \frac{m^{[4]}}{n^{[4]}} \right] & \text{if } k < \lceil n/2 \rceil. \end{cases}$$

It then follows that if  $\Omega = \mathcal{A}_n$ , we have

$$(4.12) \quad \mathbf{E}(c_1^2 + \dots + c_{n-1}^2) = \sum_{k=1}^{n-1} \left( \frac{\lambda}{4} \right) + \sum_{k=1}^{n-1} \left( \frac{\lambda(\lambda-1)}{16} \right) + \sum_{k=1}^{\lceil n/2 \rceil - 1} \left( \frac{2(\lambda-k)}{16} \right),$$

whereas if  $\Omega = \mathcal{A}_{n,m}$ , we have

$$(4.13) \quad \mathbf{E}(c_1^2 + \dots + c_{n-1}^2) = \sum_{k=1}^{n-1} \left( \lambda \frac{m^{[2]}}{n^{[2]}} \right) + \sum_{k=1}^{n-1} \left( \lambda(\lambda - 1) \frac{m^{[4]}}{n^{[4]}} \right) \\ + \sum_{k=1}^{\lceil n/2 \rceil - 1} \left( 2(\lambda - k) \left[ \frac{m^{[3]}}{n^{[3]}} - \frac{m^{[4]}}{n^{[4]}} \right] \right).$$

Recalling that  $\lambda$  is simply shorthand for  $n - k$ , it is straightforward to verify that

$$\sum_{k=1}^{n-1} \lambda = \frac{n(n-1)}{2}, \quad \sum_{k=1}^{n-1} (\lambda^2 - \lambda) = \frac{n(n-1)(n-2)}{3},$$

and that

$$\sum_{k=1}^{\lceil n/2 \rceil - 1} 2(\lambda - k) = \begin{cases} n(n-2)/2 & \text{if } n \text{ is even,} \\ (n-1)^2/2 & \text{if } n \text{ is odd.} \end{cases}$$

So, if  $\Omega = \mathcal{A}_n$ , then from (4.12) we get

$$\mathbf{E}(c_1^2 + \dots + c_{n-1}^2) = \begin{cases} \frac{1}{4} \cdot \frac{n(n-1)}{2} + \frac{1}{16} \cdot \frac{n(n-1)(n-2)}{3} + \frac{1}{16} \cdot \frac{n(n-2)}{2} & \text{if } n \text{ is even,} \\ \frac{1}{4} \cdot \frac{n(n-1)}{2} + \frac{1}{16} \cdot \frac{n(n-1)(n-2)}{3} + \frac{1}{16} \cdot \frac{(n-1)^2}{2} & \text{if } n \text{ is odd,} \end{cases} \\ = \begin{cases} (2n^3 + 9n^2 - 14n)/96 & \text{if } n \text{ is even,} \\ (2n^3 + 9n^2 - 14n + 3)/96 & \text{if } n \text{ is odd,} \end{cases}$$

which, using (2.1) and (4.9), implies

$$\mathbf{E}(\|\alpha\|_4^4) = \begin{cases} \frac{n^2+n}{4} + \frac{2n^3+9n^2-14n}{48} = \frac{2n^3+21n^2-2n}{48} & \text{if } n \text{ is even,} \\ \frac{n^2+n}{4} + \frac{2n^3+9n^2-14n+3}{48} = \frac{2n^3+21n^2-2n+3}{48} & \text{if } n \text{ is odd,} \end{cases}$$

or equivalently

$$(4.14) \quad \mathbf{E}_{\mathcal{A}_n}(\|\alpha\|_4^4) = \frac{4n^3 + 42n^2 - 4n + 3 - 3(-1)^n}{96}.$$

On the other hand, if  $\Omega = \mathcal{A}_{n,m}$ , then from (4.13) we get

$$\mathbf{E}(c_1^2 + \dots + c_{n-1}^2) \\ = \begin{cases} \frac{m^{[2]}}{n^{[2]}} \cdot \frac{n(n-1)}{2} + \frac{m^{[4]}}{n^{[4]}} \cdot \frac{n(n-1)(n-2)}{3} + \left( \frac{m^{[3]}}{n^{[3]}} - \frac{m^{[4]}}{n^{[4]}} \right) \cdot \frac{n(n-2)}{2} & \text{if } n \text{ is even,} \\ \frac{m^{[2]}}{n^{[2]}} \cdot \frac{n(n-1)}{2} + \frac{m^{[4]}}{n^{[4]}} \cdot \frac{n(n-1)(n-2)}{3} + \left( \frac{m^{[3]}}{n^{[3]}} - \frac{m^{[4]}}{n^{[4]}} \right) \cdot \frac{(n-1)^2}{2} & \text{if } n \text{ is odd,} \end{cases} \\ = \begin{cases} \binom{m}{2} + m^{[4]}/(3(n-3)) + m^{[3]}(n-m)(n^2-2n)/(2n^{[4]}) & \text{if } n \text{ is even,} \\ \binom{m}{2} + m^{[4]}/(3(n-3)) + m^{[3]}(n-m)(n^2-2n+1)/(2n^{[4]}) & \text{if } n \text{ is odd,} \end{cases}$$

which, using (2.1), implies

$$\mathbf{E}(\|\alpha\|_4^4) = \begin{cases} 2m^2 - m + \frac{2m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(n^2-2n)}{n^{[4]}} & \text{if } n \text{ is even,} \\ 2m^2 - m + \frac{2m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(n^2-2n+1)}{n^{[4]}} & \text{if } n \text{ is odd,} \end{cases}$$

or equivalently

$$(4.15) \quad \mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4) = 2m^2 - m + \frac{2m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(2n^2 - 4n + 1 - (-1)^n)}{2n^{[4]}}.$$

Notice that if  $m$  is fixed and  $n$  approaches infinity, then  $\mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4)$  approaches  $2m^2 - m$ , i.e., for fixed  $m$  and large  $n$ , we expect a random  $\alpha \in \mathcal{A}_{n,m}$  to correspond to a Sidon set, as is consistent with intuition.

If  $\Omega = \mathcal{B}_n$ , since  $\mathcal{B}_n := \mathcal{A}_{n+1} \setminus \mathcal{A}_n$ , we get

$$\begin{aligned} \mathbf{E}_{\mathcal{B}_n}(\|\alpha\|_4^4) &= \frac{1}{2^n} \sum_{\alpha \in \mathcal{B}_n} \|\alpha\|_4^4 = 2\mathbf{E}_{\mathcal{A}_{n+1}}(\|\alpha\|_4^4) - \mathbf{E}_{\mathcal{A}_n}(\|\alpha\|_4^4) \\ &= \frac{4n^3 + 66n^2 + 188n + 87 + 9(-1)^n}{96} \end{aligned}$$

by (4.14). Therefore we have proved

**Theorem 4.1** *If  $m \leq n$ , we have*

$$\mathbf{E}_{\mathcal{A}_n}(\|\alpha\|_4^4) = \frac{4n^3 + 42n^2 - 4n + 3 - 3(-1)^n}{96},$$

$$\mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4) = 2m^2 - m + \frac{2m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(2n^2 - 4n + 1 - (-1)^n)}{2n^{[4]}} \quad (\text{if } n \geq 4),$$

$$\mathbf{E}_{\mathcal{B}_n}(\|\alpha\|_4^4) = \frac{4n^3 + 66n^2 + 188n + 87 + 9(-1)^n}{96}.$$

For completeness, we also determine  $\mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4)$  when  $n \leq 3$ . If  $n \leq 3$ , we have  $\alpha(z) = a_0 + a_1z + a_2z^2$  and then

$$\begin{aligned} \|\alpha\|_4^4 &= c_0^2 + 2c_1^2 + 2c_2^2 \\ &= (a_0^2 + a_1^2 + a_2^2)^2 + 2(a_0a_1 + a_1a_2)^2 + 2(a_0a_2)^2 \\ &= a_0^4 + a_1^4 + a_2^4 + 4(a_0^2a_1^2 + a_0^2a_2^2 + a_1^2a_2^2) + 4a_0a_1^2a_2 \\ &= a_0 + a_1 + a_2 + 4(a_0a_1 + a_0a_2 + a_1a_2) + 4a_0a_1a_2, \end{aligned}$$

since  $a_j \in \{0, 1\}$  from which it readily follows that

$$\begin{aligned} \mathbf{E}_{\mathcal{A}_{2,0}}(\|\alpha\|_4^4) &= \mathbf{E}_{\mathcal{A}_{3,0}}(\|\alpha\|_4^4) = 0, \\ \mathbf{E}_{\mathcal{A}_{2,1}}(\|\alpha\|_4^4) &= \mathbf{E}_{\mathcal{A}_{3,1}}(\|\alpha\|_4^4) = 1, \\ \mathbf{E}_{\mathcal{A}_{2,2}}(\|\alpha\|_4^4) &= \mathbf{E}_{\mathcal{A}_{3,2}}(\|\alpha\|_4^4) = 6, \\ \mathbf{E}_{\mathcal{A}_{3,3}}(\|\alpha\|_4^4) &= 19. \end{aligned}$$

We remark that substituting  $m \in \{0, 1, 2, 3\}$  into the second equation in Theorem 4.1 and then formally cancelling common factors as appropriate, we get

$$\begin{aligned} \mathbf{E}_{\mathcal{A}_{n,3}}(\|\alpha\|_4^4) &= 15 + \frac{3(2n^2 - 4n + 1 - (-1)^n)}{n(n-1)(n-2)}, \\ \mathbf{E}_{\mathcal{A}_{n,2}}(\|\alpha\|_4^4) &= 6, \\ \mathbf{E}_{\mathcal{A}_{n,1}}(\|\alpha\|_4^4) &= 1, \\ \mathbf{E}_{\mathcal{A}_{n,0}}(\|\alpha\|_4^4) &= 0, \end{aligned}$$

yielding results consistent with the explicit averages just obtained for  $n \leq 3$ .

### 5 Ubiquity of Sidon Sets

We show that our expression for  $\mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4)$  yields a new proof of a result that appears in articles by Godbole et al. [4] and Nathanson [6].

Suppose  $\Omega = \mathcal{A}_{n,m}$ , and as before, denote a typical element of  $\mathcal{A}_{n,m}$  by

$$\alpha(z) = z^{\beta_1} + \dots + z^{\beta_m}.$$

Recall from Section 2 that  $X := c_1^2 + \dots + c_{n-1}^2 - \binom{m}{2}$  is a nonnegative-integer-valued random variable on  $\Omega$  that attains the value 0 if and only if  $\{\beta_1, \dots, \beta_m\}$  is a Sidon set.

We have

$$\begin{aligned} \mathbf{E}_{\mathcal{A}_{n,m}}(X) &= \mathbf{E}_{\mathcal{A}_{n,m}}(c_1^2 + \dots + c_{n-1}^2) - \binom{m}{2} \\ &= \begin{cases} \frac{m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(n^2-2n)}{2n^{[4]}} & \text{if } n \text{ is even,} \\ \frac{m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(n^2-2n+1)}{2n^{[4]}} & \text{if } n \text{ is odd} \end{cases} \\ &\leq \frac{m^{[4]}}{3(n-3)} + \frac{m^{[3]}(n-m)(n-1)^2}{2n^{[4]}} \\ &= \frac{m(m-1)(m-2)(2mn-3n-m)}{6n(n-2)} \\ &\leq \frac{m^4}{3n} \end{aligned}$$

if  $n \geq 4$ . On the other hand, if we let  $B(n, m)$  be the number of Sidon sets in  $[n]$  with  $m$  elements, then we have

$$\begin{aligned} \mathbf{E}(X) &= \frac{1}{\binom{n}{m}} \sum_{\alpha \in \mathcal{A}_{n,m}} X = \frac{1}{\binom{n}{m}} \sum_{\alpha \in \mathcal{A}_{n,m}, X>0} X \geq \frac{1}{\binom{n}{m}} \#\{\alpha \in \mathcal{A}_{n,m} : X(\alpha) > 0\} \\ &\geq 1 - \frac{1}{\binom{n}{m}} B(n, m). \end{aligned}$$

Hence we have proved (by essentially using Markov's inequality) the following.

**Corollary 5.1** For  $4 \leq m \leq n$ , we have

$$B(n, m) \geq \binom{n}{m} \left(1 - \frac{m^4}{3n}\right)$$

and

$$\Pr[\{\beta_1, \dots, \beta_m\} \text{ is Sidon}] > 1 - \frac{m^4}{3n}.$$

Hence if  $m = o(n^{1/4})$ , then as  $n$  approaches infinity, the probability that a randomly chosen  $m$ -subset of  $[n]$  is Sidon approaches 1.

Although when  $m = o(n^{1/4})$ , the probability that a randomly chosen  $m$ -subset of  $[n]$  is Sidon approaches 1 (i.e.,  $\|\alpha\|_4^4$  is  $2m^2 - m$  for almost all  $\alpha \in \mathcal{A}_{n,m}$ ), there are some other cases in which a positive proportion of polynomials in  $\mathcal{A}_{n,m}$  have very large  $L_4$  norm.

For  $\alpha \in \mathcal{A}_{n,m}$ , since for  $0 \leq k \leq n - 1$ ,  $c_k = \sum_{j=0}^{n-k-1} a_j a_{j+k}$ , we have  $c_0 = m$ , and for  $1 \leq k \leq n - 1$ ,  $|c_k| \leq \min\{m - 1, n - k\}$ . Therefore, we have

$$\begin{aligned} \|\alpha\|_4^4 &= c_0^2 + 2 \sum_{k=1}^{n-1} c_k^2 \leq m^2 + 2 \sum_{k=1}^{n-m+1} (m - 1)^2 + 2 \sum_{k=n-m+2}^{n-1} (n - k)^2 \\ &= 2nm^2 - \frac{4}{3}m^3 + 4m^2 - 4nm + 2n - \frac{5}{3}m \\ &= 2(1 + o(1))m^2 \left(n - \frac{2}{3}m\right) \end{aligned}$$

if  $n = o(m^2)$  as  $m, n \rightarrow \infty$  and on the other hand, from (4.15) we have

$$\begin{aligned} \frac{2(1 + o(1))m^4}{3n} &\leq \mathbf{E}_{\mathcal{A}_{n,m}}(\|\alpha\|_4^4) = \frac{1}{\binom{n}{m}} \sum_{\alpha \in \mathcal{A}_{n,m}} \|\alpha\|_4^4 \\ &= \frac{1}{\binom{n}{m}} \left\{ \sum_{\|\alpha\|_4^4 \leq x} \|\alpha\|_4^4 + \sum_{\|\alpha\|_4^4 > x} \|\alpha\|_4^4 \right\} \\ &\leq x + \frac{1}{\binom{n}{m}} \sum_{\|\alpha\|_4^4 > x} \|\alpha\|_4^4 \\ &\leq x + \frac{1}{\binom{n}{m}} \sum_{\|\alpha\|_4^4 > x} 2(1 + o(1))m^2 \left(n - \frac{2}{3}m\right). \end{aligned}$$

It then follows that for any  $x < 2(1 + o(1))m^4/(3n)$ , we have

$$\frac{\#\{\alpha \in \mathcal{A}_{n,m} : \|\alpha\|_4^4 > x\}}{\binom{n}{m}} \geq \frac{2(1 + o(1))m^4/(3n) - x}{2(1 + o(1))m^2(n - 2m/3)}.$$

In particular, for any  $\epsilon > 0$ , if  $m = c_1 n$  and  $x = c_2 m^2 n$  for  $0 < c_1 < 1$  and  $0 < c_2 < 2(1 - \epsilon)c_1^2/3$ , we have

$$\frac{\#\{\alpha \in \mathcal{A}_{n,m} : \|\alpha\|_4^4 > c_2 m^2 n\}}{\binom{n}{m}} \geq \frac{2(1 - \epsilon)c_1^2/3 - c_2}{2(1 + \epsilon)(1 - 2c_1/3)} > 0$$

for sufficiently large  $n$  and  $m$ , i.e., there is a positive proportion of polynomials in  $\mathcal{A}_{n,m}$  having large  $L_4$  norm (note that the  $L_4$  norm in  $\mathcal{A}_{n,m}$  is at most as large as  $2(1 + o(1))m^2 n$ ).
